1 Importance Sampling with Resampling

Sequential Monte Carlo

- 4 ロ b 4 個 b 4 差 b 4 差 b - 差 - 夕久で

"10" 10/30/19 2/24

Adding Resampling

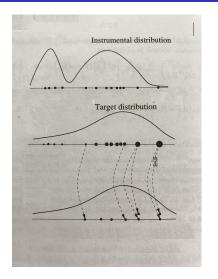

Importance Sampling gives you weighted draws $(\theta^1, w(\theta^1)), (\theta^2, w(\theta^2)), \dots$

You can draw from these, with replacement. At the expense of more variance, it will give you unweighted draws from your target distribution: $\tilde{\theta}^1, \tilde{\theta}^2, \ldots$

This is known as **factored sampling** or **importance sampling with resampling** or **sampling importance resampling** (SIR).

Adding Resampling

Original, unedited image is from https://www.springer.com/us/book/9780387402642

SIR

Stage 1: do importance sampling to get $\{\theta^i, w(\theta^i)\}_{i=1}^S$.

Stage 2: for i = 1, ..., S, select

$$P[\tilde{\theta}^i = \theta^j \mid \theta^1, w(\theta^1), \dots, \theta^S, w(\theta^S)] = w(\theta^j).$$

Example 2 revisited

```
y <- 2 # fake data
log_unnorm_weight <- function(theta){</pre>
  # can ignore sqrt(2pi) because it will cancel out
  -.5*(y - theta)^2
num_samples <- 10000
theta_draws <- rt(num_samples , 1)</pre>
lunws <- log_unnorm_weight(theta_draws)</pre>
# note: prob arg automatically normalizes
random_indexes <- sample(x = num_samples,
                          size = num_samples,
                          replace = T,
                          prob = exp(lunws))
sort(random_indexes) # see there are repeats!
resampled_draws <- theta_draws[random_indexes]</pre>
hist(resampled_draws) # can't do this unless we resample
```

Other uses of importance (re)sampling

• Use importance resampling for obtaining starting points for an iterative simulation of the posterior distribution, as in Chapter 11.

"10" 10/30/19 7/24

Other uses of importance (re)sampling

- Use importance resampling for obtaining starting points for an iterative simulation of the posterior distribution, as in Chapter 11.
- Calculation of intractable quantity under a change of model. Posterior under the previous model: $p_1(\theta|y) \propto q_1(\theta|y)$ $\theta^1, \ldots, \theta^S \sim p_1(\theta|y)$ Posterior after a change of model: $p_2(\theta|y) \propto q_2(\theta|y)$ We need $E_2(h(\theta)|y)$

Resampling adds variance, so why do it?

It throws away bad samples, and duplicates promising ones.

When you're looking at a sequence of distribution targets, this can have a good effect on future samples.

"10" 10/30/19 8/24

Resampling adds variance, so why do it?

It throws away bad samples, and duplicates promising ones.

When you're looking at a sequence of distribution targets, this can have a good effect on future samples.

sequential monte carlo or **particle filtering** methods are basically doing SIR over and over again.

At "time" t-1 you just resampled, so you have draws $\tilde{\theta}_{t-1}^1, \tilde{\theta}_{t-1}^2, \dots, \tilde{\theta}_{t-1}^S$, and you want to turn them into draws for the next "time" period:

$$\tilde{\theta}_t^1, \tilde{\theta}_t^2, \dots, \tilde{\theta}_t^S.$$

"10" 10/30/19 8/24

Examples of sequences of distributions

Data annealing¹

$$p(\theta), p(\theta \mid y_1), p(\theta \mid y_{1:2}), \ldots, p(\theta \mid y_{1:n}),$$

Temperature annealing²

$$p(y \mid \theta)^{a_0} p(\theta), p(y \mid \theta)^{a_1} p(\theta), \dots p(y \mid \theta)^{a_n} p(\theta)$$

with
$$0 = a_0 < a_1 < \cdots < a_n = 1$$
.

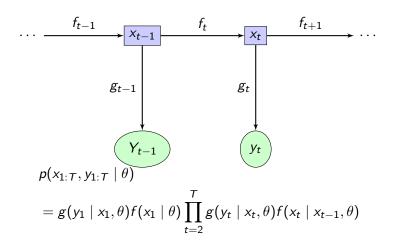

filtering and smoothing in state space models

$$p(x_1 \mid y_1, \theta), \ldots, p(x_n \mid y_{1:n}, \theta)$$

state space models

"10" 10/30/19 10/24

Example: filtering in state space models

Here's an example of a state space model. y_t is a univariate time series, and x_t is a hidden/unobserved/latent time series.

$$y_t = \exp(x_t/2)\epsilon_t \tag{1}$$

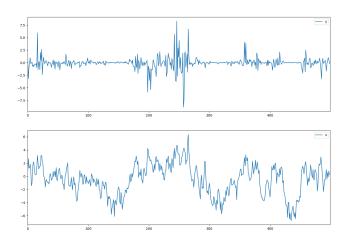

$$x_t = c + \phi x_{t-1} + v_t \tag{2}$$

We sometimes refer to (1) as $g(y_t \mid x_t, \theta)$ or the observation equation, and (2) as the state transition equation or $f(x_t \mid x_{t-1}, \theta)$.

"10" 10/30/19 11/24

Example: filtering in state space models

 $y_{1:t}$ observed, $x_{1:t}$ hidden. Goal: $p(x_t \mid y_{1:t})$ in real-time.

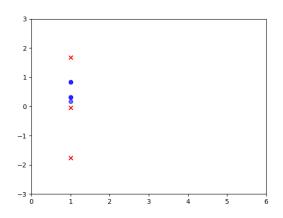

"10"

"10" 10/30/19 21/24

"10" 10/30/19 22/24

Filtering recursions

Drop dependence on θ from the notation...

$$p(x_{1:t}|y_{1:t}) = C_t^{-1} p(x_t, y_t \mid x_{t-1}) p(x_{1:t-1} \mid y_{1:t-1})$$

$$= C_t^{-1} \frac{p(x_t, y_t \mid x_{t-1})}{q_t(x_t \mid y_t, x_{t-1})} \times q_t(x_t \mid y_t, x_{t-1}) p(x_{1:t-1} \mid y_{1:t-1})$$

$$= C_t^{-1} \frac{g(y_t|x_t) f(x_t|x_{t-1})}{q_t(x_t|x_{t-1}, y_t)} \times q_t(x_t \mid x_{t-1}, y_t) p(x_{1:t-1} \mid y_{1:t-1})$$

Repeat through time:

- start with samples from $p(x_{1:t-1} \mid y_{1:t-1})$
 - **2** mutate/propogate/extend using $q_t(x_t \mid x_{t-1}, y_t)$
 - **3** adjust weights by multiplying by $\frac{g(y_t|x_t)f(x_t|x_{t-1})}{q_t(x_t|x_{t-1},y_t)}$
 - resample, giving you particles distributed as $p(x_{1:t} \mid y_{1:t})$
